Abstract

Silica porous materials with use of the some of ionic liquids (ILs) based N, N-dimethyl aminopyridinium cation (DMAP) with high thermal stability was prepared.
First according to a proper sol-gel method, various RTILs with anions such as= Br, BF_4 as a new kind of recyclable templates in present of trimethoxy silane (TMOS) as the sol-gel precursor and deionized water were employed. Then ILs was removed from the silica matrix by calcination method.
The resulting gels were characterized by using thermogravimetric analysis, infrared spectroscopy. The calcined gels were analyzed using scanning electron microscopy and X-ray diffraction. In the continuous, reaction was fallowed under acidic conditions at temperature above the melting point of the functional IL such as; 2–ethoxyethyl-4-(N, N-dimethyl amino) pyridinum tetrafluoroborate with larger hydrophilic polar region in a so-called nanocasting sol-gel technique, those silica nanostructured materials with highly ordered monolithic was obtained.

Keywords: Sol-Gel process; N, N-dimethyl amino pyridinium ionic liquid; Nanostructured material; Silica; Ionogel.

Introduction

Silica based sol–gel technique has attracted a considerable interest because it has proven to be a convenient route for the preparation of hybrid compounds which combine characteristics of organic and inorganic components and applied widely in many fields, such as optical devices, sensor sciences and catalysis [1–3]. Sol–gel process is mild, which proceeds by hydrolysis of an alkoxide precursor and followed by polycondensation of the hydroxylated monomers to form a porous gel. Under this mild polymerization process, sol–gel hybrids could be easily produced by impregnates of organic reagents or copolymerization with the high reactivity of silanol by covalent bonding. The studies suggested that the properties of the sol–gel hybrids could be tuned by designing the sol–gel matrix with suitable materials.

Ionic liquids (ILs) are composed entirely of ions, which exist in liquid state at temperatures around 298 $^{\circ}$K and below. As a potentially environmentally benign reaction media, ILs have attracted more considerable attention for their unique chemical and physical properties, such as high thermal stability, high ionic conductivity, negligible vapor pressure and adjustability of characteristics via choice of the anion and cation combination etc [4-5].

Recently, ILs have been used in the preparation of sol–gel materials [6–13]. In sol–gel applications, ILs have served as solvents [6, 8, 12], pore templates [7, 9], drying control chemical additives [10], and possibly as a catalyst [12]. In several cases, ILs had significant effects on the porous structure of sol–gel materials [7,10,12], reduction in cracking and shrinking [10,11,14] during solvent evaporation from the sol–gel pores, and sol–gel reaction kinetics [10,12,15,16]. Based on unique properties of ionic liquid and advantages of sol–gel technique, new kind of hybrid materials that combine ILs with sol–gel appeared and had promising applications in preparation of nano-materials, catalysis and biosensor [17–22], Shi et al. also synthesized [RDMAP][X] based sol–gel hybrids material and characterized the resulting matrix representing crack-free morphology because the viscous IL prevented the cracking of the sol–gel derived glasses [19-21].

In this work, according to a proper sol-gel method, various RTILs with various cations and anions as templates were used. (Scheme 1). And effect of the cations and anions in ILs on morphology and structure of the calcined silica Nanostructured materials investigated. We showed that these compounds not only for solvent, but also act as catalysis in sol-gel processes.

Experimental

Materials and reagents

All the chemicals used in the present work were purchased from Merck and used as received.

Measurements

Thermogravimetric analyses (TGA) of the air-dried gels were performed on a TGA/SDTABSI thermogravimetric Analyzer (METTLER TOLEDO). Samples were heated under an argon atmosphere on room temperature to

650°C at 10 $^{\circ}$C min^{-1}. X-ray diffraction (XRD) patterns were performed on a D$_8$ADVANCE (BRUKER axs) powder X-ray diffractometer. Diffraction patterns were recorded with Cu Ka radiation (40 mA, 40 kV) over a 2θ range of 1.2^0 -15^0 at a scan rate of 2℃/min.

The calcined gels were characterized using scanning electron microscopy (SEM) (Philips XL30 S-2500), infrared spectroscopy (BRUKER PS15), infrared spectroscopy (IR) (BRUKER PS15) with a Perkin-Elmer. DSC differential scanning calorimeter at a heating rate of 10°C/min in air.
Scheme 1. Reactions processes for Ionic liquids Synthesis

Synthesis of ionic liquid compounds:

The synthetic procedure of ILs followed a reported route [23]. 1.22g, (10 mmol) DMAP(dimethyl amino pyridine)was added to a 50 ml three- necked round-bottom flask containing (10mmol) of anyone of compounds; 1-Bromobutane, 1-Bromopentane, 1-Bromo ethoxyethane, 1-Bromopentyne, respectively in acetonithrile and 1-Bromododecane,in dichloromethane as solvent of reaction. The mixture was heated to reflux with constant stirring for 10 h, and then cooled to room temperature. The volatile component was removed under reduced pressure to give the crude product. This compound was dispersed into ethyl acetate- isopropanol with ratio of (1:1) from which IL$_n$ recrystallized. Then (10 mmol) of ILs in 10 ml dry CH$_2$Cl$_2$ was added to a solution of NaBF$_4$ (1.09g, 10mmol) dissolved in 40 ml of dry methanol. The mixture was stirred at room temperature for 20 h and then all solvents were removed.

The resulting residue was dissolved in CH$_2$Cl$_2$ and it was filtered to remove NaBr, and ionc liquids of [C$_2$C$_3$DMAP][BF$_4$],[C$_2$OC$_2$DMAP][BF$_4$] was resulted, but [C$_4$DMAP][BF$_4$], [C$_5$DMA][BF$_4$]was purified by column chromatography (Al$_2$O$_3$), with acetonithrile as the movable phase.
Preparation of silica Nanostructured materials with ILs ([RDMAP][X]) as the catalysis

In a typical synthesis with IL$_1$ as catalysis, tetramethylorthosilicate (TMOS) was used as the sol-gel precursor. Compound IL$_1$ (0.2 g, 1.69 mmol) was dissolved in 0.3 ml deionized water and a few minutes was heated until 60 ℃. This was allowed to cool to room

temperature, then (0.625 ml) TMOS monomer was added and the mixture vortexed until a monophasic solution was obtained. Gels were stored in covered vials with punched pin-holes for a one week period to allow slow evaporation of the volatile components. IL_1 was removed from the silica by calcinations of the sample at 550°C with a temperature ramp

of 5 °C/min, and then was allowed to cool to room temperature with a temperature ramp of 20 °C/min. The final product was ground into a powder for further characterization. The other Nanostructured materials were prepared by repeating above procedure with the corresponding IL_s as catalysis.

Scheme 2. Chemical structures of a) IL_1: 1-butyl -4-(N,N-dimethylamino) pyridinium tetrafluoroborate($C_4DMAPBF_4$), b) IL_2: 1-pantyl -4-(N,N-dimethylamin) pyridiniumbromid and c) IL_3: 1-panty-4 -(N,N-dimethylamino) pyridinium tetrafluoroborate ($C_5DMAPBr,BF_4$), d) IL_4 :1- pantinyl -4-(N,N- dimethylamino) pyridiniumtetafluoroborate ($C_2C_3DMAPBF_4$), e) IL_5:1-dodecyl -4-(N,N-dimehylamino) pyridiniumbromide($C_{12}DMAPBr$), f) IL_6: 2– Ethoxyethyl-4-(N,N-dimethylamino) pyridinium tetrafluoroborate ($C_2OC_2DMAPBF_4$).

Preparation (Sg - C_2OC_2DMAP) nanocomposite under acidic condition

In this procedure 0.2g $C_2OC_2DMAPBF_4$ was mixed with 10ml of tetraethyl-ortho silicate (TEOS) and 7ml ethanol under mild magnetic stirring. After homogenization, 2 ml of concentrated hydrochloride acid (36–38%) diluted by 3.5ml of distilled water was added and

the mixture became coagulated gradually. After aged at 60 ℃ for 12 h, the resulted solid material was dried in vacuum at 120℃ for 4 h. Then $C_2OC_2DMAPBF_4$ were extracted from silica matrix by refluxing the synthesized Sg-C_2OC_2DMAP BF_4(0.5g) in 200 mL of methanolic solution of HCl (0.5M) for 48 h.

Results and discussion

Some ionic liquids: ([R DMAP][X]) in which R = Bu, pentyl), pentynyl, 2–ethoxyethyl, and dodecyl were synthesized. DMAP was reacted with alkyl bromides in which R=Bu, pentyl, pentylyl, ethoxyethyl, and dodecyl to produce some novel ionic liquids with bromide as an anion. Then anion exchange reaction was done with some anions such as $NaBF_4$ (Scheme 1). These compounds were characterized by ^1H, ^{19}F NMR and IR spectroscopic methods. The results are given below (Scheme1):

C₄DMAPBF₄ (n=1)

IR (KBr) cm^{-1} = 3030 (Ar C-H); 2932 (aliphatic C–H); 1651, 1571(Ar C=C); 726 (B-F).

Characterization of gels

SEM characterization of calcined silica Nanostructured materials

Figure (1) shows the the SEM images of the resulting calcined silica Nanostructured materials froma molar ratio described of silicon precursor tetramethyl ortho silicate, water, and ionic liquid based N,N-dimethyl aminopyridinium cation for (a) IL$_1$, (b) IL$_2$, (c) IL$_3$, (d) IL$_4$, (e) IL$_5$, (f) IL$_6$. The ILs was used as a template in a traditional manner. SEMs of the gels revealed a mareked effect as the structure of IL was changed. Also these images show that the average particle size is below 100 nm.

 Naught observation of particle in image of (f$_1$) relatead to hydrophilic polar region of IL$_5$; C$_2$OC$_2$DMAPBF$_4$, with the ether moiety close to the N,N- dimethyl aminopyridinium group, is significantly larger of others. And as a result, increase the polar region of ionic liquid increase the polar region of ionic liquid increase percent hydrogen bonding of pyridinum ring with Si-OH groups. That was prevented the formation of Si-O-Si bonds from condensation polymerization pathway. Also such hydrogen bonding would help disrupt any ring stacking compared to other ILs. Zhou et al [24] suggested a worm-hole effect (ordered periodicity) and the formation of long channels (image of a, c, d).

 On the other hand performance of reaction under acidic condition, in the presence of organic solvent of ethanol and IL$_6$ as a catalysis and also stabilization the reaction temperature in 60 °C for 12 h during the aging process, hydrolysis process accelerate, and the aging gelation was accomplished. During this period IL is molten and acts as an active supermolecule catalysis. In addition IL has a longer time for orientation porous silica framework. And as a result, silica framework was obtained

with more ordered, highly porous, more uniform surface (image of f_2).

According to image of (e) in present IL_5 with long molecular chain as template; the macroporosity decreased, and a more uniform topography was observed [25]. This problem related to an increased thermal stability of IL with long molecular chain linked to N, N-dimethyl aminopyridinium cation to allow the condensation, and densification process are done in longer time in high temperatures.

In the C_2C_3DMAP BF_4 (IL4) duo to formation $\pi - \pi$ stacking pyridinium rings with pentyne alkyl chain according to Scheme (2), a ununiform morphology, size and shape was obtained(image of d).

X-ray diffraction data of calcined silica Nanostructured materials

XRD spectrum in (Figure 3) do not show any clue for the formation of crystallized silica, indicating that the silica gel materials obtained in the presemce of IL_n based N,N- dimethyl aminopyridinium cation as template are amorphous, and even after being calcined at $550^\circ C$ do not observe any peak [26]. But silica porous material that synthesized in the presence of $C_{12}DMAPBr$ template exhibits a distinct diffraction peak at $2\theta = 2.40$. With the corresponding d spacing about 17.5 nm, which in good agreement with the SEM observation.

Thermogravimetric analysis of the gels

The results of thermogravimetric analyses (TGA) traces of the air-dried gels are shown in table 1. Tg is decomposition temperature of the IL as the matrix of sol gel. As a result the

thermal stability ILs based N, N-dimethyl aminopyridinium cation is higher than ILs based imidazolium cation. Also the large polar region in C_2OC_2DMAP based IL, due to more hydrogen bonding with matrix silica cause higher thermal stability in silica network.

On the other hand ionic liquids of long molecular chain as template was obtained micellar and packing structures from silica sol gel materials and remove this ILs was achived in higher temperatures according with result of table(1). Also exchanging anion from Br to BF_4 was increased thermal stability, that attributed to the $\pi - \pi$ stacking of the pyridinium rings and formation of hydrogen bonding between the tetrafluoroborate anion and the hydroxyl groups of the silica. The schematic illustration of the mechanism is presented in the Scheme (2), that indicates $\pi - \pi$ stacking of the pyridinium rings is more efficient than stacking of the imidazoliumrings.

Invistigation of Infrared spectroscopic characterization

Infrared spectroscopy of the non-calcined gels (Figure 4-a) showed small peaks at areas 2900 and 2800 cm^{-1}, corresponding to the N,N-dimethyl aminopyridinium cation alkyl groups and any residual methoxy groups of the silica monomer. This show that in non- calcined gel, IL is in matrix. IL is blocking the complete reaction of the monomer. These peaks are presented in all non-calcined gels. But the optimum hydrolysis conditions corresponding in the acidic environment, sharp peakes are invisible (Figure 4-c).

Also, the two characteristic bands of the N,N- dimethyl aminopyridinium ring around 1600-1570 cm^{-1} could not be observed in the spectra of calcined gels(Figure 4-b).of course this bonds adsorption in hybrid C_2OC_2DMAP- Sg under acidic condition are as one broadband, indicating that a strong interaction between the pyridinium group and the silica matrix (Figure 4-c).

Figure 3. XRD patterns of calcined silica sol–gel materials of the (a) Sg-C_{12}DMAPBr, (b) Sg-[RDMAP][X]. [RDMAP]; R=$C_{4, C5,}$ C_2C_3, C_2OC_2 [X] = Br, BF_4

Figure 4. IR spectra of silica sol–gels: (a) non-calcined silica sol–gel; (b) calcined sol–gel synthesized with IL; (c)Sg-C_2OC_2DMAP nanocomposite under acidic condition.

Scheme 4-a, b. Illustration of the synthesis of silica-gel-confined ionic liquids.as catalysis: Sg: Sol-gel; IL:[RDMAP][X]:R=C_4,C_5, C_{12},C_2C_3, C_2OC_2; [X]= Br, BF_4

Conclusion

Silica Nanostructured materials with various RTILs based N, N-dimethyl amino pyridinium cation with high thermal stability as templates were synthesized according to a proper sol–gel method.

The results show that, with using various kind of ILs, various morphology, particle size, and shape was obtained. The best result was obtained in which functional ILs was used. In this case a uniform morphology, size, and shape were produced. This is especially interesting case in selective drugs loading, drugs delivery systems, and selective analytical application. In comparison hydrophilic polar region and hydrophobic region of ionic liquids C_2OC_2DMAP, $C_{12}DMAPBr$, as surfactant in synthesis of silica Nanostructured materials, it was observed that with increasing hydrophobic region of IL silica frameworks with miceller and highly ordered structures was obtained. On the other hand, variety of procedure is important in synthesis, and topography of Nanostructured silica materials. In

this procedure the structure of ILs important factor. And as a result of the controlled periodic porosity silica materials was obtained by using of [$C_{12}DMAP$][Br] as template whit long alkyl chain and also highly ordered monolithic silica Nanostructures were prepared under acidic conditions at temperatures above the melting points of the IL ([C_2OC_2DMAP][BF_4]) in a so-called nanocasting sol-gel technique.
